ASLV Rockets:

The ASLV, Augmented Satellite Launch Vehicle or Advanced Satellite Launch Vehicle is a five-staged solid fuel rocket developed by the Indian Space Research Organisation (ISRO) to place 150kg satellites into LEO. This project was started by India during the early 1980s to develop technologies needed for a payload to be placed into a geostationary orbit. Its design was based on Satellite Launch Vehicle (SLV).The payloads of ASLV were Stretched Rohini Satellites. The ASLV was a five-stage vehicle. Two strap-on boosters for the first stage with the core stage igniting after booster burn out. The payload capacity of the ASLV was approximately 150kg to an orbit of 400km with 47-degree inclination. At lift-off, the ASLV generated 92,780kgf of thrust. It was a 41,000kg rocket, measuring 23.5m in length with core diameter of 1m.

Flight No.	Date	Payload	Payload Mass	Launch Outcome
D1	24th March 1987	SROSS-A	150kg	Failure
D2	13th July 1988	SROSS-B	150kg	Failure
D3	20th May 1992	SROSS-C	106kg	Partial Failure
D4	5th May 1994	SROSS-C2	113kg	Success
